1. Propose new for (t) from $q(j | old = (t-1))$. 2. Compute the ratio $r = \frac{p(new)q(old | j)}{p(old)q(new | old)}$. 3. If $r \geq 1$, set (t) = new; If $r < 1$, set (t) = old with probability r and new with probability $1 - r$. Then a draw (t) converges in distribution to a draw from the true posterior density $p(j)$.

Using a π at prior on y , i.e., $\pi(y) \propto 1$, we have $\log(\pi(y)) = \log(f(y)) + C = y \log + (n - y) \log(1 - y) + C$. The first derivative is given by $\log'(y) = \log\left(\frac{f(y)}{1 - y}\right)$.

$\frac{\partial \log L(\theta)}{\partial \theta} = 0$: Equating to zero and solving for θ gives the posterior mode $\hat{\theta}$.
 $\frac{\partial^2 \log L(\theta)}{\partial \theta^2} \Big|_{\theta = \hat{\theta}}$: The second derivative is given by $\frac{\partial^2 \log L(\theta)}{\partial \theta^2} \Big|_{\theta = \hat{\theta}}$.

Those interested in learning how to run and diagnose Bayesian regression in R will find almost everything they need to know here. As with many R texts, Bayesian Computation with R has an accompanying package of functions available on CRAN (“LearnBayes”). The functions in this package are focused mainly on teaching Bayesian analysis, but also include some useful basic implementations.

Bayesian Computational Analyses with R is an introductory course on the use and implementation of Bayesian modeling using R software. The Bayesian approach is an alternative to the "frequentist" approach where one simply takes a sample of data and makes inferences about the likely parameters of the population. In contrast, the Bayesian approach uses both likelihood functions and a sample of observed data (the 'prior') to estimate the most likely values and distributions for the estimated ...
